#### **RATIONALE**

The real-time continuous monitoring of surface parameters is very important for different applications, like risk management, natural hazards and land surveillance. Geostationary platforms allow to provide series of satellite observations with a very high temporal resolution, able to resolve the diurnal cycle and to catch seasonal variability. In this work the development of a very fast multi-temporal and multi-spectral Level 2 processor is described. The processor exploits SEVIRI (Spinning Enhanced Visible and Infrared Imager) infrared radiances (8.7, 9.7, 10.8 and 12 μm) to retrieve surface temperature and emissivity simultaneously by means of a fast forward radiative transfer model (σ-SEVIRI) and an inversion procedure based on the Kalman filter approach. Further details on the adopted methodology are reported in recent works (Masiello et al. 2013 doi:10.5194/amt-6-3613-2013), together with validation exercises at regional and global scale both against in situ, analysis and equivalent satellite observations (Masiello et al. 2015 doi:10.5194/amt-8-2981-2015; Blasi et al. 2016 doi: 10.3369/tethys.2016.13.01). The software is capable to run in real-time also thanks to a code optimization and the usage of parallel computation. In detail, a single SEVIRI full disk slot time (15 minutes) can be processed in about 16 minutes exploiting 20 threads, providing surface temperature and emissivity estimations on land surface.

### Forward Model: σ- SEVIRI, pseudo-monochromatic radiative transfer model $R(\theta_r, \varphi_r, \sigma) = \varepsilon(\theta_r, \varphi_r, \sigma)\tau_0(\theta_r, \varphi_r, \sigma)B(T_s) + R_u(\theta_r, \varphi_r, \sigma) + R_r(\theta_r, \varphi_r, \sigma)$ $R_{u}(\theta_{r}, \varphi_{r}, \sigma) = \int_{0}^{\infty} B(T) \frac{\partial \tau}{\partial h} dh$ It takes into account both Specular $R_r(\theta_r, \varphi_r, \sigma) = \tau_0(\theta_r, \varphi_r, \sigma) \int_0^{2\pi} d\varphi_i \int_0^{\frac{\pi}{2}} f(\theta_r, \varphi_r, \theta_i, \varphi_i, \sigma) R_i(\theta_i, \varphi_i, \sigma) \cos\theta_i \sin\theta_i d\theta_i$ and Lambertian reflection New forward model: PCA (Principal Component Analysis) based approach to Radiative Transfer Model About 7 times faster than older $\sigma$ -SEVIRI version $[n_c \times 1]$ $[n_p \times n_c]$ $[n_c \times 1]$ $[n_l \times 1]$ $[n_l \times n_p]$ Inverse Model: δ-SEVIRI, Kalman Filter + Persistence Model for the simultaneous retrieval of surface temperature and emissivity $\begin{cases} \mathbf{R}_{t} = F(\mathbf{v}_{t}) + \mathbf{\epsilon}_{t} & \longrightarrow \text{observation equation} \\ \mathbf{v}_{t+1} = \mathbf{H}\mathbf{v}_{t} + \mathbf{\eta}_{t} & \longrightarrow \text{state/evolution equation} \end{cases}$ analysis at time t update or analysis $\int \hat{\boldsymbol{v}}_{t} = \hat{\boldsymbol{v}}_{a} + \left(\boldsymbol{K}_{t}^{T}\boldsymbol{S}_{\epsilon}^{-1}\boldsymbol{K}_{t} + \boldsymbol{S}_{a}^{-1}\right)^{-1}\boldsymbol{K}_{t}^{T}\boldsymbol{S}_{\epsilon}^{-1}\left(\boldsymbol{y}_{t} - \boldsymbol{K}_{t}\left(\hat{\boldsymbol{v}}_{a} - \boldsymbol{v}_{o}\right)\right)$ $\left| \mathbf{S}_{t} \neq \left( \mathbf{K}_{t}^{T} \mathbf{S}_{\varepsilon}^{-1} \mathbf{K}_{t} + \mathbf{S}_{a}^{-1} \right)^{-1} \right|$ forecast covariance of $\eta_{t}$ $\begin{cases} \hat{\mathbf{v}}_{t+1}^f = \mathbf{H}\hat{\mathbf{v}}_t \\ \hat{\mathbf{S}}_{t+1}^f = \mathbf{H}\hat{\mathbf{S}}_t\mathbf{H}^T + \mathbf{S}_{\eta}^T \end{cases}$ forecast at time t

**METHODOLOGY** 

## **Results on Land Surface** Surface Temperature, °C Full Disk (VZA<=70°): Total 3,545,871 pixels for Land 3,488,328 Land pixels **57,543** In Land Water pixels **Monthly Map (November 2007) of KF SEVIRI surface temperature** Monthly Maps (November 2007) of KF SEVIRI emissivity (8.7, 10.8 and 12 micron) AVHRR NDVI (Nov 2007) Emissivity Contrast Index (Nov 2007) $\delta \epsilon = Max(ChEmiss) - Min(ChEmiss)$ We define the Emissivity Contrast Index (ECI) as $1-\delta\epsilon$ . ECI varies in range [0,1]: **ECI≈1, NDVI ≈1: Green Vegetation** ECI≈1, NDVI ≈0: Dry Vegetation ECI≈0, NDVI ≈0: Bare Soil Monthly Maps (Nov 2007) of SEVIRI ECI and AVHRR NDVI to assess the synergy ECI-NDVI (IR-VIS) Emiss Index Jun-Nov 2015 **ECI variations** Emiss Contrast Index (Jun-Nov 2015) Secretary and the second second □ For water $ECl \approx 0.99$ For bare soil ECI is between **0.7-0.8** For green vegetation ECI is in the range 0.98-1 (high emissivity since it

is structured and contains water)

For dry or senescent vegetation, ECI

is expected between 0.94-0.98 (in

this case emissivity is more variable,

especially in the 3-5 μm region,

depending on the type and

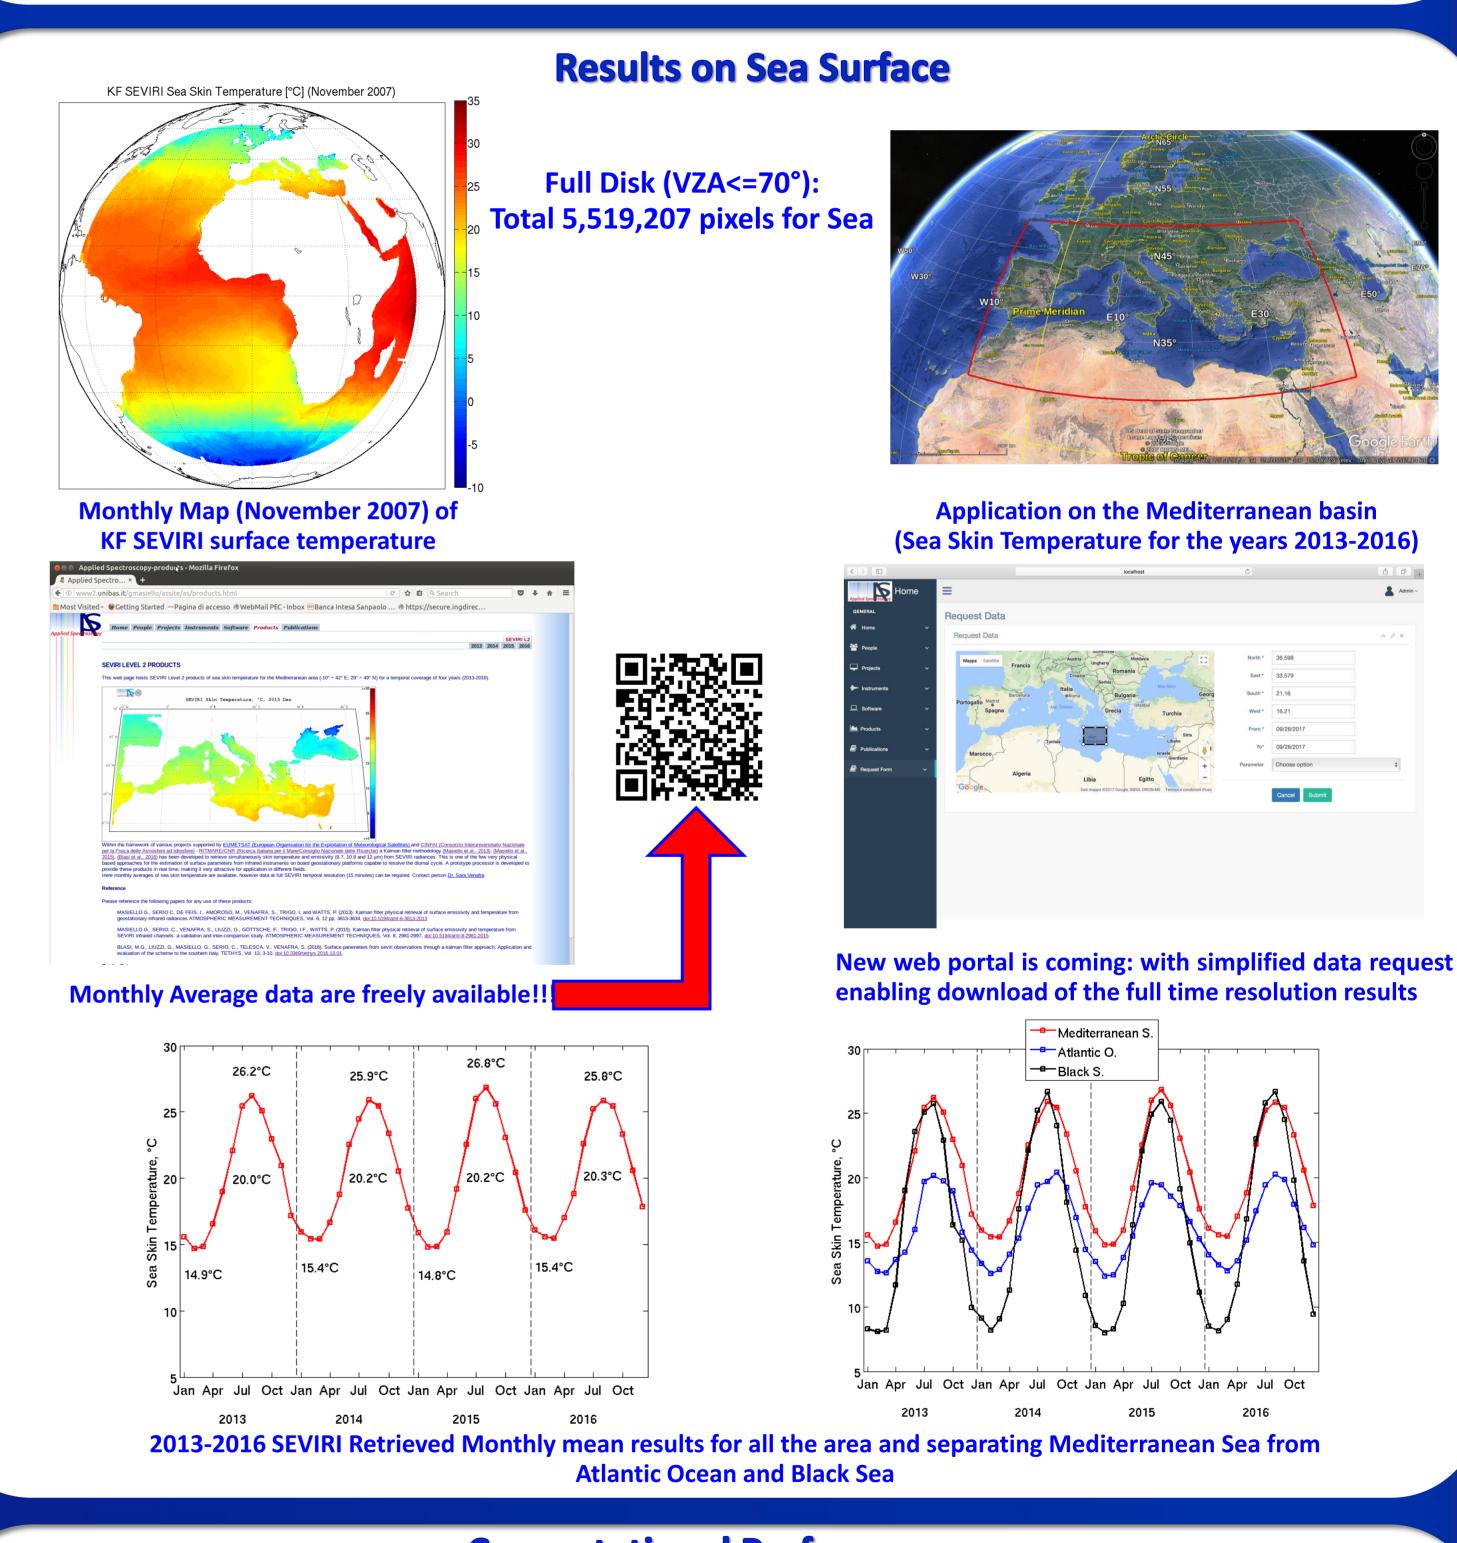

structure of cover type, the dryness,

Emis Index vs SM (Dry Pixels)

ECI and its correlation with Soil Moisture has been assessed mostly for semi-arid and arid lands, the case of SINAI-NEGEV desert

0.77

Correlation between ECI and Soil Moisture (from HSAF) for wet and dry pixels

### **Computational Performances**

A single SEVIRI FD run (for land pixels) takes about 30 minutes exploiting 8 threads and considering all pixels as clear sky (Ifort Compiler). For the Mediterranean area (232,898 pixels) it takes about 15 minutes exploiting one thread and considering all pixels as clear sky. These performances make this first fully based physical scheme very attractive for real-time applications.

### **CONCLUSIONS & FUTURE DEVELOPMENTS**

□ The physical simultaneous retrieval of surface emissivity and temperature has been applied to the SEVIRI full disk;

The model has been improved and now it is about 7 times faster than previous version;

The algorithm can be specialized for land or sea or both and a land-based version has been integrated and tested on IPMA LSA-SAF virtual machines for full disk retrieval of surface temperature and emissivity; The emissivity contrast index (ECI) can distinguish between bare soil and dry vegetation;

There is a need to investigate ECI-NDVI synergy. In perspective this could improve SEVIRI capability to monitor vegetation stress and detect changes because of the global warming.
