Outline

- Background: Arctic System Reanalysis (ASR) Project
- Preliminary Results from 2 test periods
- Summary and future work

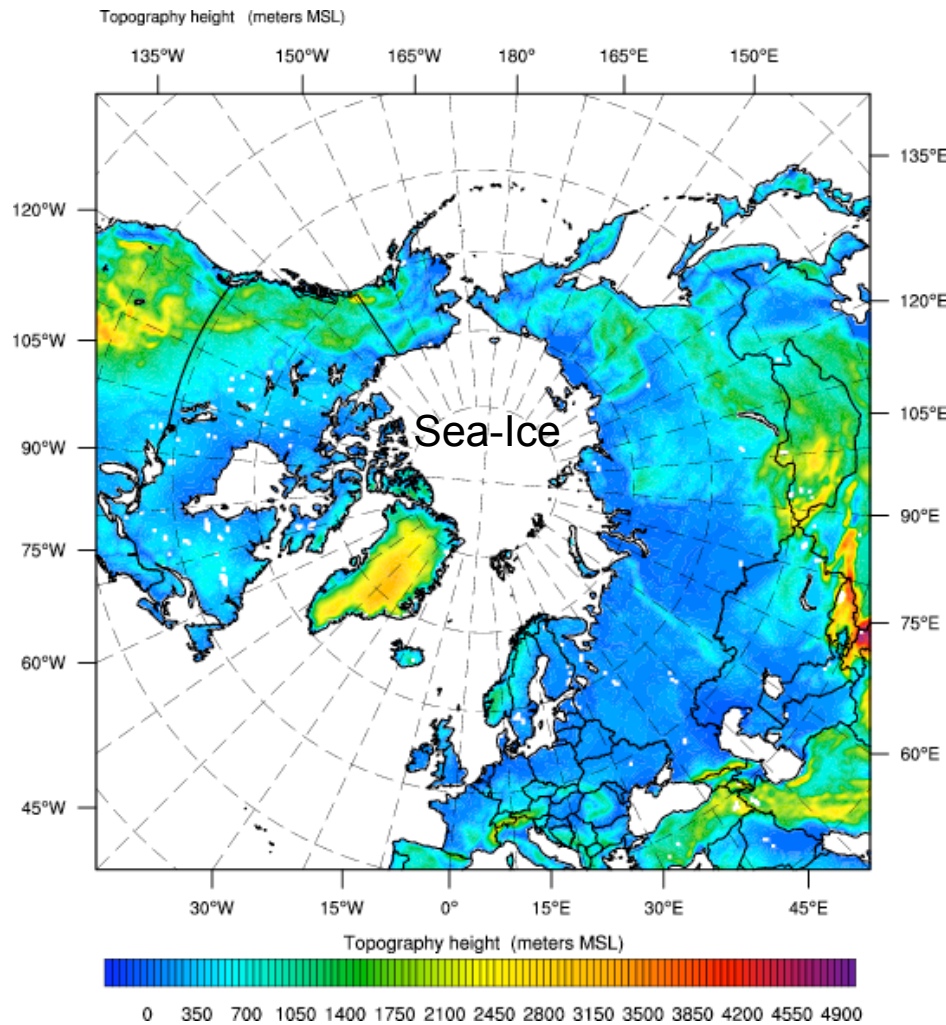

Background

- Arctic System Reanalysis (ASR) project
 - Funded by US NSF
 - University efforts: OSU, NCAR, UIUC, CU
 - 11 years reanalysis: 2000~2010
 - Currently testing for 30km, may go up to 10km?
 - NCEP provided conventional and radiance data.
- Testing/Tuning the system for 2 months
 - Dec. 2007: use NCEP FNL (1°X1°, P levels) as LBC
 - Aug. 2008: use ERA-Interim (80X80km, model level) as LBC

WRFDA-3DVAR

- WRFDA includes 3D/4DVAR and Hybrid VAR/Ensemble scheme
- 3DVAR is adopted for ASR for computational efficiency
 - 3-hr cycling regional DA, time window: ± 1.5 h
- Control variables: stream function, unbalanced velocity potential, unbalanced T, pseudo RH, unbalanced Ps.
- NMC method to generate background error covariance statistics.
 - Domain-averaged statistics.
- Recursive filter in horizontal, EOF in vertical for covariance modeling.

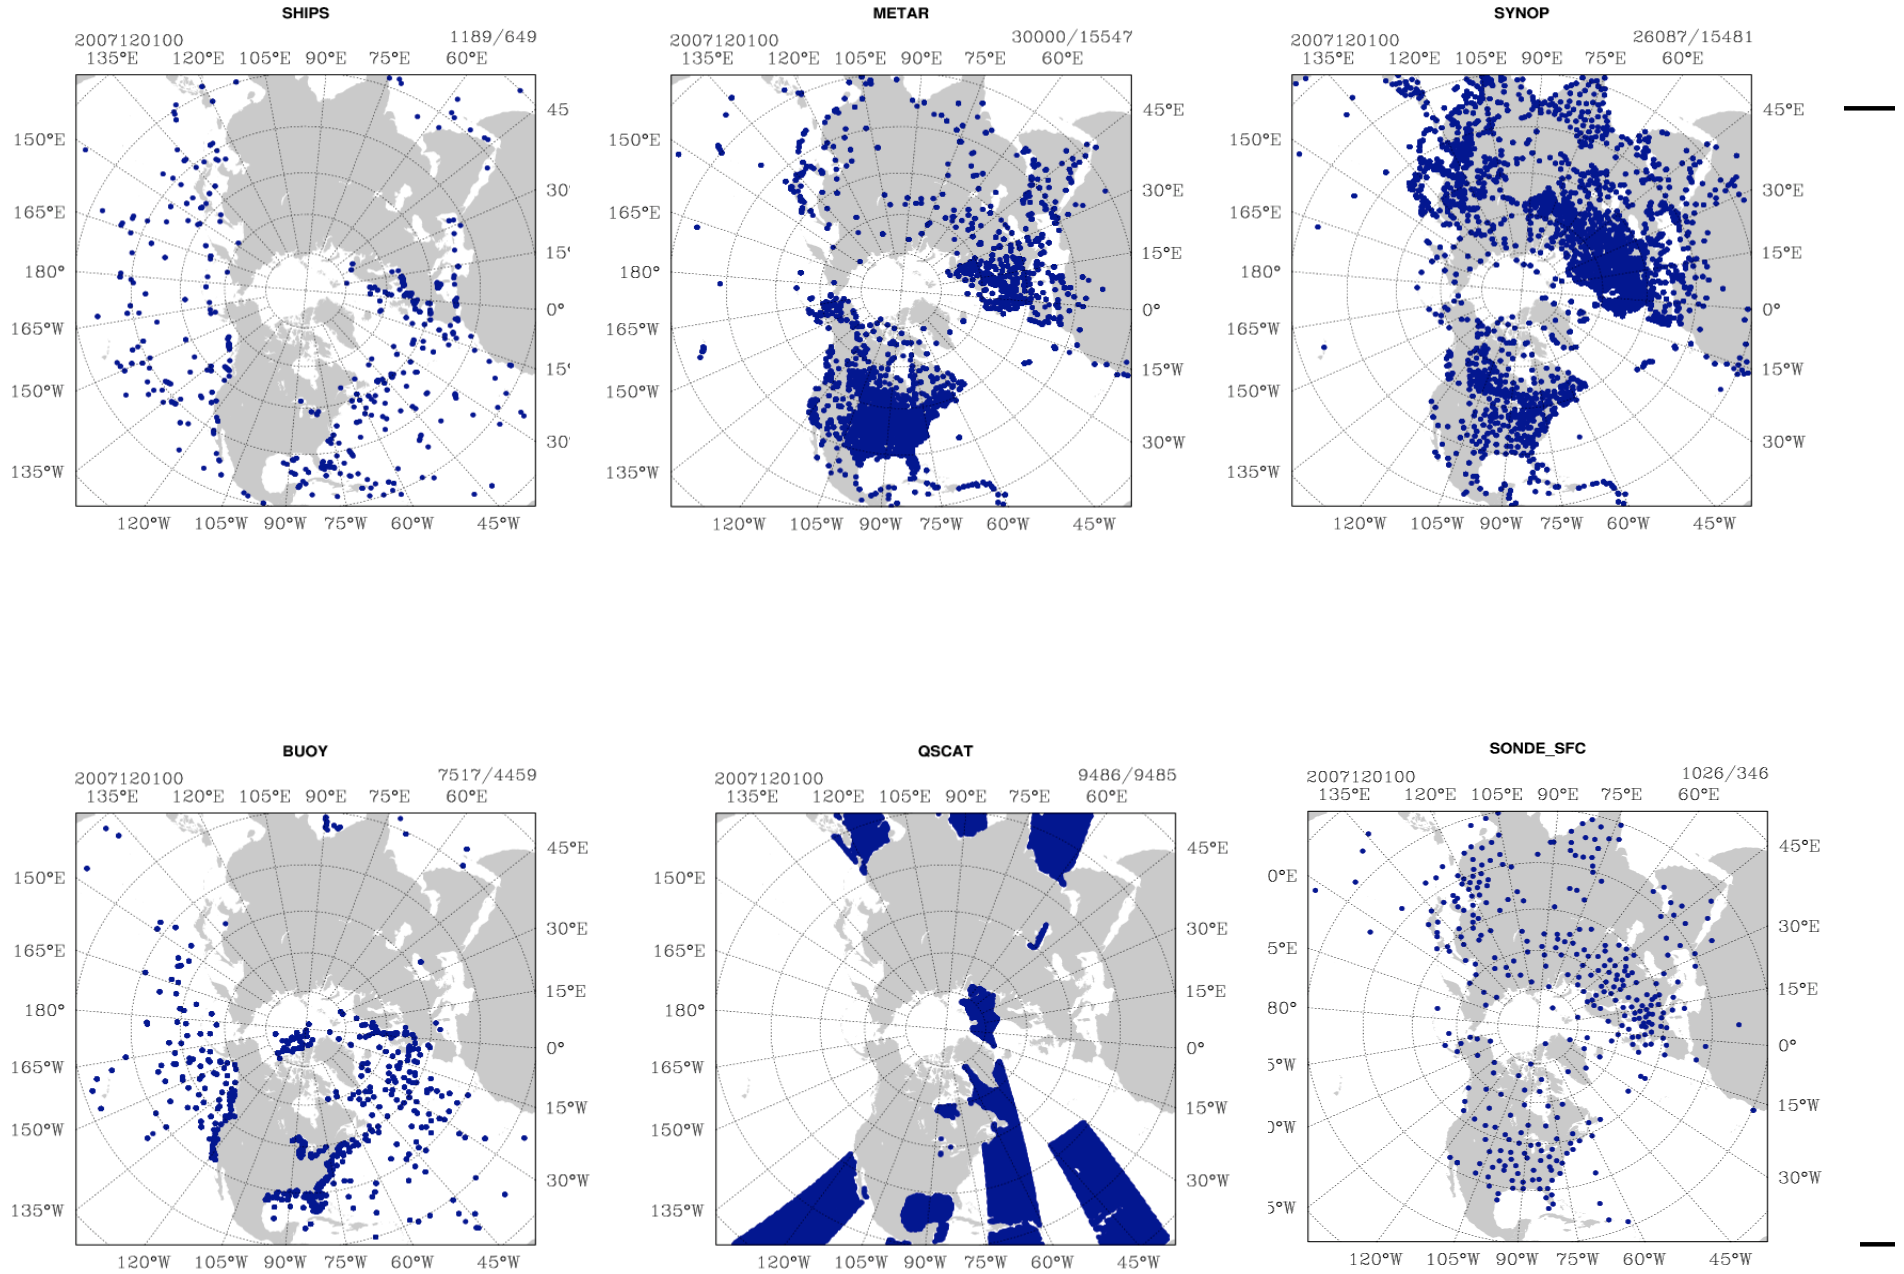

ASR domain

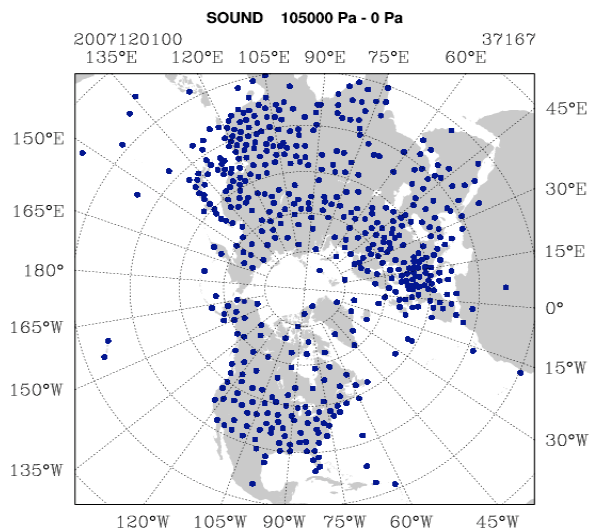

WRF model version 3.1:
30km*30km (360*360),
70 Levels (Top@10hPa)
40m-50m vertical spacing in PBL

DFI, GWD, fractional sea-ice
WSM5 MP, new Grell,
MYNN2.5 PBL, sw/lw RRTMG,
Noah LSM.

NCEP PREPBUFR data (2007120100, +/-3h time window)

GPSRO data caused large cold biases near model top due to bad quality control (data above 30km not rejected).

Will re-include in future exps. with refined QC.

Radiance data used

	amsua	amsub	mhs
Noaa-15	4,5,6,7,8,9	3,5	
Noaa-16	4,5,6,7,8	3,4,5	
Noaa-17		3,4,5	
Noaa-18	4,5,6,7,8		3,4,5
Metop-2	4,5,6,8,9		3,4,5
Aqua	4,5,6,8,9		

Follow NCEP provided instrument/Channel availability table
AMSU-A ch4 only over sea
Thinning to 90km.
CRTM, Variational Bias Correction

AIRS new cloud detection scheme was found instable.
May include it in future runs.

Summary

- Several issues in WRFDA were found during testing
 - GPSRO QC, AIRS cloud detection scheme.
 - Errors near the model top increasing with the time.
 - Other issues not listed/mentioned in this talk
- Radiance impact is mixed
 - Adding radiances tends to produce more precip. over ocean.
 - Better positioning Low pressure centers over ocean
 - Radiances apparently improve T2m/Q2m.
 - But larger Ps error.
 - Mixed impact for upper air. Model top biases make things complicate.
- Difficulties to do reanalysis for university.
 - Computational resource limitation, limited man power
 - Data collection/processing
 - Lack detailed obs monitoring information (usually available in operational NWP centers. e.g., blacklist of various obs types)

Future work

- More testing/tuning needed before production run
 - Diagnose HBH^T and compare to R
 - Use observation sensitivity tools to identify impact from different obs types (& individual radiance channel)
 - Model top issue: nudging global fields at top levels? increase model top? Add O3?
- Need run forecasts to judge analysis performance.
