NOAA Regional Models

NAM+Nests

RAP/HRRR

HiResWs

RRFSv1 Computational Domain

Next Generation Regional Model RRFS

- Based on the FV3 dynamical core Limited Area Model (LAM) capability
- Convection-allowing (~3 km grid spacing)
- Model grid 3950x2700
- 65 vertical layers with 2-mb model top
- GSI Hybrid 3DEnVar assimilation (30-40 members)
- Rapidly updated (hourly)
- Deterministic forecasts to 18h every hour
- Ensemble forecasts to 60h every 6 hours
- Implementation Fall, 2024

Satellite Data Tested in RRFs

AMSU-A

NOAA-15 Channels 1-5,7-10, 15
NOAA-18 Channels 14,6-7, 10, 15
NOAA-19 Channels 16, 9-10, 15
METOP-A Channels 16, 9-10, 15
METOP-B Channels 8,13
METOP-C Channels 110, 15

MHS

NOAA-18 Channel 15
NOAA-19 Channels 1-2, 4-5
METOP-B Channels 15
METOP-C Channels 15

ABI

GOES16 Channels 8-10 (CSR)

ATMS

NOAA-NPP Channels 1-11,16-22
NOAA-20 Channels 1-11, 16-22

CRIS

NOAA-NPP CrIS 72 Channels
NOAA-20 CrIS 72 Channels

IASI

IASI METOP-A 98 Channels
IASI METOP-B 98 Channels
IASI METOP-C 98 Channels

SSMIS

F17 Channel 57

Objectives

- Re-address the bias correction of satellite radiance within this new RRFS system by evaluating the performance of existing bias correction initialization and cycle strategies
- Compare cycling bias coefficients independently in the RRFS by adopting bias coefficients from the global model (GFS)

Variational Bias Correction (VarBC)

(Dec, 2004; Auligné et al. 2007, Zhu et al. 2014)

Linear predictor model for bias in each channel:

$$\mathbf{b}(\mathbf{x}, \boldsymbol{\beta}) = \sum_{i=0}^{N_p} \beta_i \mathbf{p}_i(\mathbf{x})$$

Cost function:

$$J(\mathbf{x}, \boldsymbol{\beta}) = \underbrace{(\mathbf{x}_b - \mathbf{x})^T \mathbf{B}_x^{-1} (\mathbf{x}_b - \mathbf{x})}_{\mathbf{J}_x: \text{background constraint for } \mathbf{x}} + \underbrace{(\boldsymbol{\beta}_b - \boldsymbol{\beta})^T \mathbf{B}_\beta^{-1} (\boldsymbol{\beta}_b - \boldsymbol{\beta})}_{\mathbf{J}_\beta: \text{background constraint for } \boldsymbol{\beta}} + \underbrace{[\mathbf{y} - \mathbf{b}(\mathbf{x}, \boldsymbol{\beta}) - h(\mathbf{x})]^T \mathbf{R}^{-1} [\mathbf{y} - \mathbf{b}(\mathbf{x}, \boldsymbol{\beta}) - h(\mathbf{x})]}_{\mathbf{J}_o: \text{bias-corrected observation constraint}}$$

$$\mathbf{B}_\beta^{(i)} = \text{diag}(\sigma_{\beta_{i,j}}^2, \dots, \sigma_{\beta_{n,j}}^2)$$

σ_β^2 is set to be the estimate of the analysis-error variance of the predictor from the previous analysis cycle, which is automatically adjusted within GSI **without proportion** to the number of radiance data. However, there is a threshold (obs number < 20) in GSI to control if the variance will be updated from the analysis cycle.

Bias correction experiments

Retrospective testing (May 11-19, 2021) for 3-km CONUS domain

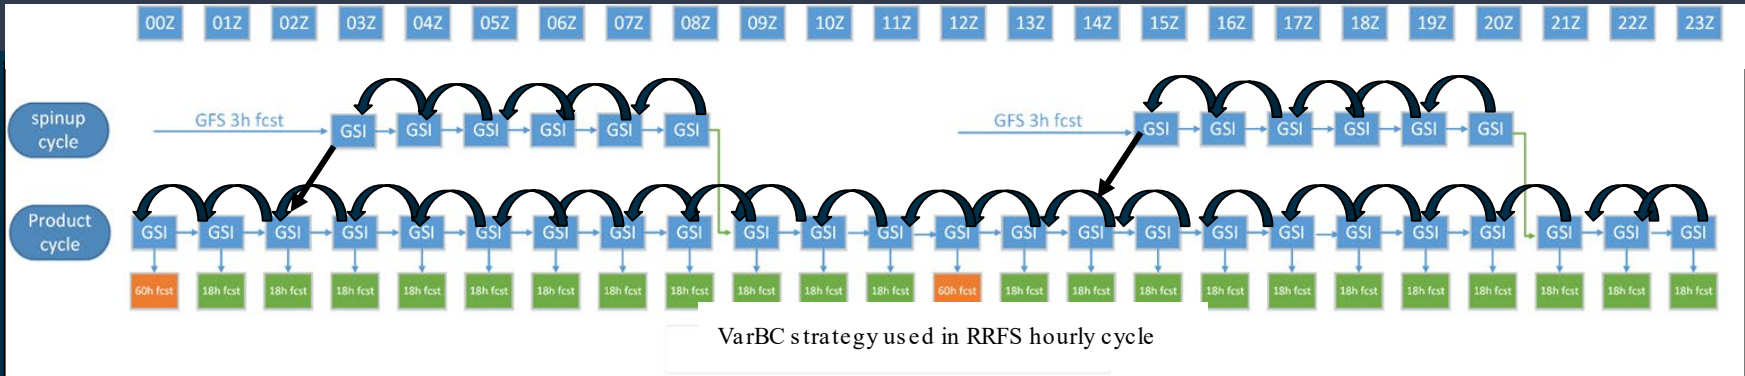

Experiment Name	Initialisation type	Initialisation bias coefficient	Cycle update
1. Exp: bias0	Cold start	Zero	Hourly
2. Exp: biasg	Warm start	Global	Hourly
3. Exp: biasgl	Warm start	Global	Fixed

RRFS DA bias correction cycle strategy

1

00Z global bias

06Z global bias

12Z global bias

18Z global bias

3

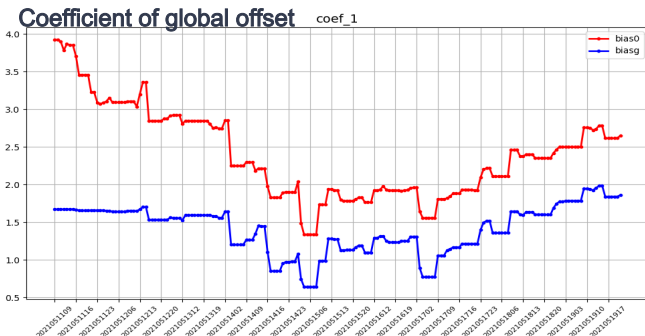

Time series of amsua_n19 channel 1:

- Number of data
- Background error variance of global offset
- Bias coefficient of global offset

The background variance is the estimate of the analysis error variance of the predictor coefficient from previous analysis cycle. Large background variance leads to a large adjustment to the predictor coefficient. The adjustment of bias coefficient largely correlated to observation number in regional DA

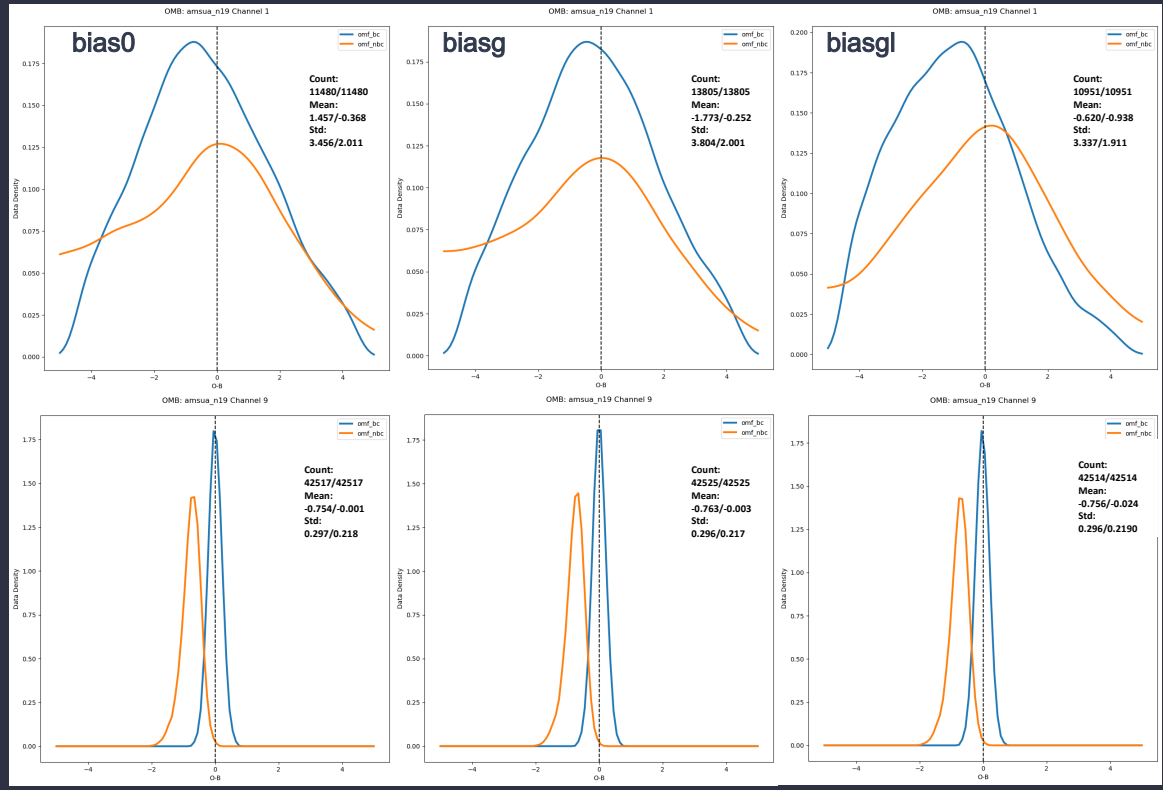

In GSI, when the data amount less than certain threshold (<20), the background variance multiplied by the factor (1.1)

The adjustment of bias coefficient Initialized from zero or from global has the same trend when spin-up settled.

O-B histogram of amsua_n19 channel 1 & 9 before and after bias correction

- The O-B fit after bias correction is different among three experiments of surface channel.
- The O-B of surface channel has larger cold bias with bias corrected from fixed global bias coefficient
- For higher peaking channel, the three bias correction strategies performed very similar.

Total bias time series of amsua_n19 channel 1& 9

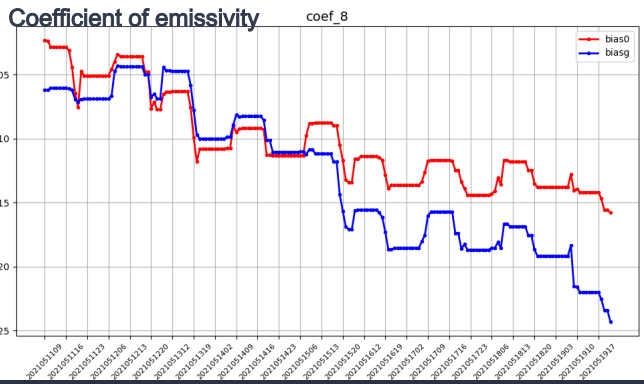

In the RRFS system, the bias estimate is highly variable in time, but global system bias estimate is relatively less variable, especially for near-surface channel.

Issue in CrIS_N20 channel 125:

- Bias coefficient continued drifting, and the coefficient dropped dramatically at a certain time when the data count increased.
- Surface emissivity coefficient has the same drifting problem as global offset term.

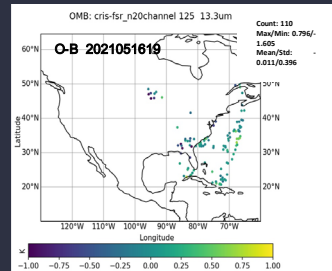

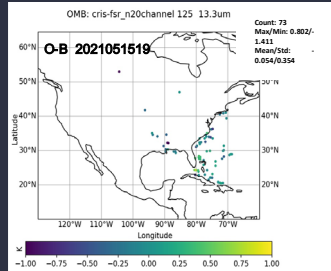

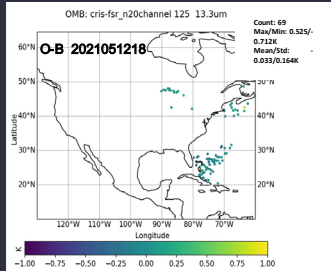

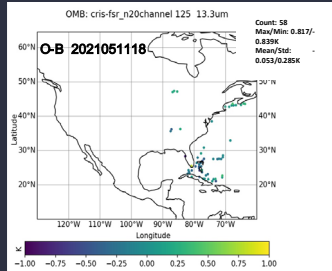

Issue in CrIS_N20 channel 125 Cont.

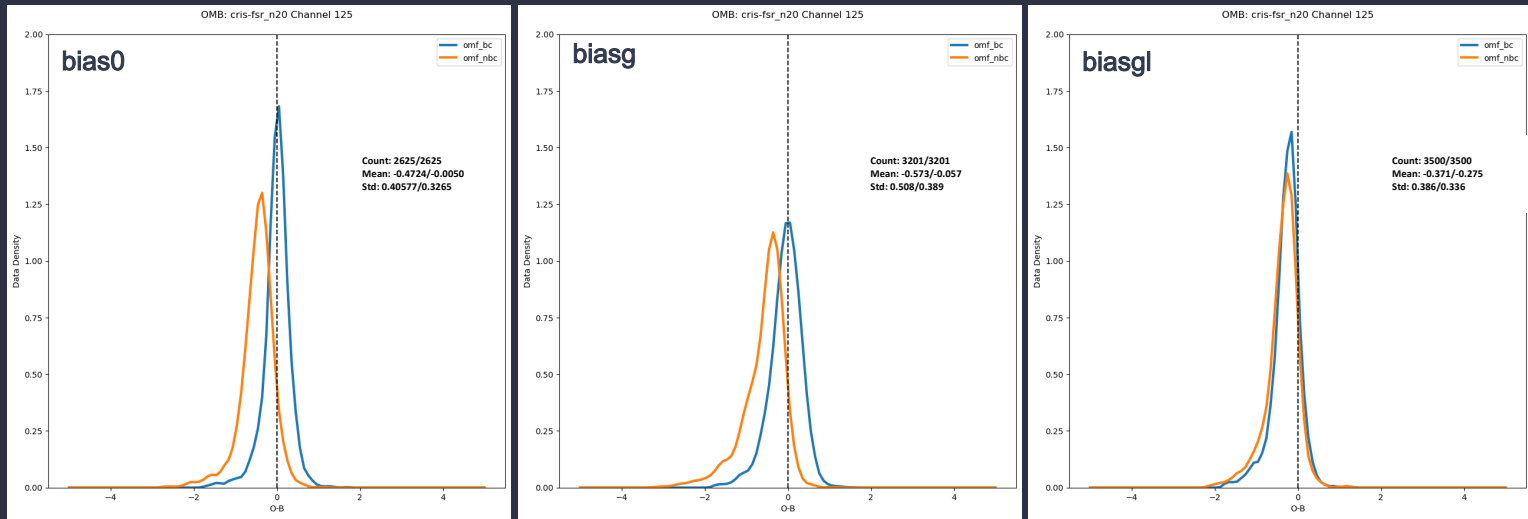

- The time of bias coefficient dropped significantly corresponding to the time of most data over the ocean
- GSI QC rejects all CrIS obs over non-sea surfaces with a surface-to-space transmittance > 2%.

O-B histogram with/without bias correction of crs_n20 channel 125

before and after bias correction

- The experiment initialized the bias coefficient from zero has the best O-B fit
- Coefficient adjustment drifting issue do not make the bias correction to a wrong direction

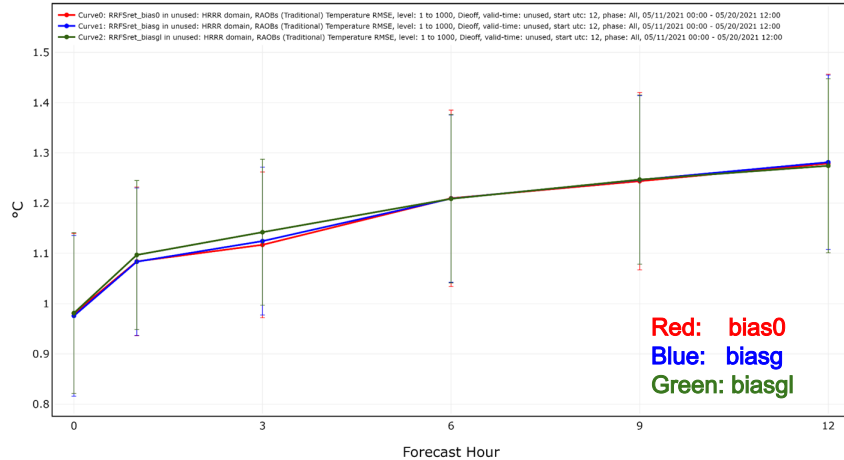

Bias correction impact on 12-hour Forecast

Upper Air : DieOff: no diffs MATCHED

Curve0 mean = 1.52, median = 1.53, stdev = 0.026
Curve1 mean = 1.52, median = 1.52, stdev = 0.044
Curve2 mean = 1.51, median = 1.47, stdev = 0.0934

Temperature forecast

Upper Air : DieOff: no diffs MATCHED

Curve0 mean = 13.38, median = 14.37, stdev = 1.889
Curve1 mean = 13.98, median = 14.63, stdev = 1.916
Curve2 mean = 14.30, median = 14.70, stdev = 1.822

RH forecast

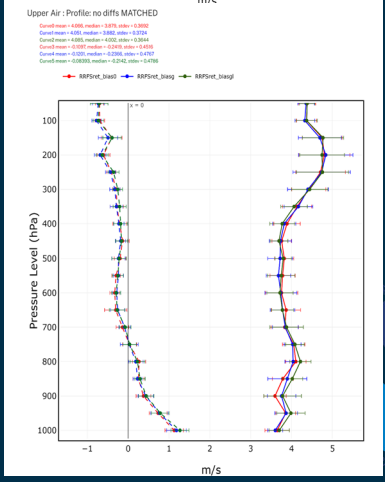

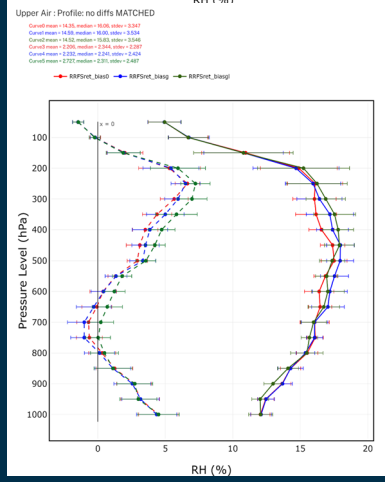

- The experiment initialized the bias coefficient from zero has the best forecast for temperature 1-6 hours forecast, for RH 1-9 hours forecast.
- Wind forecast is very similar from all experiments, the figure is omitted here.

Upper Air Forecast Verification RMSE & Bias

Experiment **bias0** has the best 3/ 6-hour forecast for RH in middle and upper troposphere; there is better temperature forecast at lower troposphere.

Summary

- ❖ Three bias correction initialization and cycle strategies were assessed in RRFS
 - The best forecast performance for temperature and relative humidity was by cycling a bias coefficient independently in the RRFS hourly analysis cycle, and initializing the bias coefficient from zero
 - The forecast initialized the bias coefficient from global bias coefficient is slightly worse than from zero bias coefficient, but much better than adopt the fixed global bias coefficient without cycle in RRFS
- ❖ The VarBC scheme in GSI can automatically adjust the bias coefficient error variance without proportion to the number of radiance data. It can handle properly the situation of small number of observation available in the hourly RRFS analysis cycle; but more effort is needed to address bias correction when the data distribution is over an inconsistent surface from cycle to cycle
- ❖ Based on the results of this study, the VarBC of operational RRFS will cycle the bias coefficient with hourly cycling strategy and initialization of zero

Thank You!
